

1. Server

```
○ (base) stg-edu-136-168-54-198:Lab_6 noahgallego$ python udp_server.py
Starig up on localhost port 65432
Waiting for message ...
Received 44 bytes from ('127.0.0.1', 63609)
b'This is the message. It will be repeated! :)'
Sent 44 bytes back to ('127.0.0.1', 63609)
Waiting for message ...
□
```

a.

2. Client

```
● (networks) stg-edu-136-168-54-198:Lab_6 noahgallego$ python udp_client.py
Sending b'This is the message. It will be repeated! :)'
Waiting for a response...
Received b'This is the message. It will be repeated! :)' from 127.0.0.1
Closing Socket
○ (networks) stg-edu-136-168-54-198:Lab_6 noahgallego$ □
```

a.

The server starts and listens for messages. Once the client is started, it sends a message to the port where the server is listening. Once it is received, it is acknowledged and the socket is closed. This is different because we are sending under UDP in opposition to TCP where a three-way handshake is required. From my research UDP is often used when delivery stability is not required (e.g. video streaming).
